

ABSTRACT OF THE DISCLOSURE

A radio communication network includes a plurality of base station receivers coupled to a switch for communication with at least one mobile station. A network monitoring device queries the switch for data related to the radio coverage provided by the communication network and, in response, the switch sends the data to the monitoring device. A report is generated that is related to the data received by the switch. The report indicates areas of the communication network providing deficient or redundant radio coverage in the communication network.
